57 **1. Introduction**

58 1.1 Background of formulation of guidelines

59 In the Paris Agreement adopted in 2015, the long-term goal was set of keeping the increase in the  
60 global average temperature to well below 2°C above pre-industrial levels. However, reports from  
61 IPCC and other documents suggest that if the current concentration status of greenhouse gases (GHG)  
62 in the atmosphere continues, it will be difficult to achieve the above long-term goal. To tackle this  
63 issue, the development of technologies for capturing and storing CO<sub>2</sub> from the atmosphere (negative  
64 emission technologies; NETs, or carbon dioxide removal; CDR methods), as well as technologies for  
65 effectively using CO<sub>2</sub> captured from exhaust gas (carbon recycling) and storing it (Carbon Capture,  
66 Utilization and Storage; CCUS) is underway in recent years.

67 However, there are many unclear points in their overall effectiveness because these technologies  
68 consume energy and resources and emit CO<sub>2</sub> and other GHG in processes including carbon capture  
69 and sequestration or storage. Furthermore, the influence of the storage duration and by-products, and  
70 their side effects on nature are highly uncertain. For these reasons, quantitative assessments of impacts  
71 of NETs and CCUS technologies using life cycle assessment (LCA) is encouraged.

72 The NETs Research Project is a working group in the Life Cycle Assessment Society of Japan to  
73 collect and systematically organize cases of existing LCA research on NETs and CCUS in order to  
74 discuss precautions that should be considered when setting assumptions and other factors for  
75 appropriate LCA practice. In addition, we recognized that not only assessment of NETs, but also CCUS  
76 under which technologies are shared with NETs, is useful in the establishment of a future industry map  
77 of NETs. In the project; therefore, we have defined a term, Carbon Removal and Recycling  
78 Technologies (CR2 technologies), which collectively refer NETs, CCUS, and other technologies that  
79 share fundamental technologies with NETs, and set the entire CR2 technologies as the scope of our  
80 project.

81 This document provides guidance on how to quantitatively account the amount of greenhouse gas  
82 emission in each CR2 technology, which have been discussed in our project.

83

84 1.2 Purpose and scope of the guidelines

85 The guidelines provide the methods to account the amount of the GHG emission and removal  
86 through introduction of CR2 technologies in the span of the whole life cycle.

87 However, if emissions of remarkable substances other than GHG and/or large-scale of resource  
88 consumption are expected, remarks on them should be made.

89

90 1.3 Relationships with existing standards/guidelines

91 This document was prepared with reference to the following international standards.

- 92 • ISO 14040: 2006 Environmental management — Life Cycle Assessment — Principles and  
93 framework
- 94 • ISO 14044:2006 Environmental management — Life Cycle Assessment — Requirements and  
95 guidelines
- 96 The evaluation methodology in the document is organized in align with the following guidelines  
97 and others.
- 98 • The Institute of Life Cycle Assessment, Japan: Guidelines for Contributed Amount in GHG  
99 Reduction (provisional translation), <https://www.ilcaj.org/lcahp/doc/guideline20150224.pdf>
- 100 • Ministry of Economy, Trade and Industry: Guidelines for Quantification of Contributed Amount  
101 in GHG Reduction (provisional translation),  
102 <https://www.meti.go.jp/press/2017/03/20180330002/20180330002-1.pdf>
- 103 • IPCC: 2006 IPCC Guidelines for National Greenhouse Gas Inventories
- 104 • IPCC: 2019 Refinement to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories
- 105 • Müller, L. J. et al. 2020: A guideline for life cycle assessment of carbon capture and utilization.  
106 *Frontiers in Energy Research* 8: 15.
- 107 • For matters not listed in these guidelines, refer to the above standards and guidelines.

108

#### 109 1.4 Utilization of guidelines

110 These guidelines assume that researchers and development practitioners concerning CR2  
111 technologies calculate the amount of GHG emission and removal due to CR2 technologies and use the  
112 results inside the organization as well as for communication with outside organizations through  
113 academic presentations and descriptions in the CSR report and other documents.

114 These guidelines also assume to be used by parties including the national government, autonomous  
115 bodies, and industrial groups as a guide for implementations of measures to reduce the amount of  
116 GHG emission through CR2 technologies.

## 117 **2. Definition of Carbon Removal and Recycling Technologies (CR2 technologies)**

118 In this document, CR2 technologies are defined as an integration of “NETs” and “systems in which  
119 technologies that can emit GHG through the use of fossil fuel and CCUS technologies are combined.”  
120 Technologies that can emit GHG through the use of fossil fuel refer to technologies that emit GHG  
121 not only due to the use of fossil fuel, but also from industrial processes themselves. NETs are defined  
122 as “technologies that capture GHG from the atmosphere, and store and sequester it” with reference to  
123 the broad definition “intentional human efforts to remove CO<sub>2</sub> emissions from the atmosphere” by  
124 Minx et al. (2018).

125 In this document, the amount of GHG emission to the atmosphere through CR2 technologies (or  
126 amount of GHG removed from the atmosphere) is determined as follows. A negative obtained value

127 means a net removal of GHG from the atmosphere.

128

129 (GHG emission amount balanced by CR2 technologies)

130 = (Amount of GHG generated by using raw materials and fossil fuel)

131 + (Amount of GHG emission due to introduction of CR2 technologies)

132 - (Amount of GHG stored/sequestered due to introduction of CR2 technologies)

133 .....Formula (1)

134

135 In Formula (1), when the source of the GHG captured by CR2 technologies is not from technologies  
136 using raw material and fossil fuel (when GHG captured by the NETs do not include GHG originated  
137 from technologies using fossil fuel), the first term on the right side is omitted, but the second and third  
138 terms are included.

139 Details of the first, second, and third terms on the right side in Formula (1) are shown in 3.5.1, 3.5.2,  
140 and 3.5.3, respectively.

141

142 Note 1: Examples of the calculation of GHG emission amount balanced by various CR2  
143 technologies are shown Appendix.

144 Note 2: The GHG in the third term of the right side in Formula (1) does not include naturally  
145 occurring GHG stored/sequestered from natural CO<sub>2</sub> dome, as often seen in current CO<sub>2</sub> EOR.

### 146 3. Methods of calculating GHG emissions by CR2 technologies

#### 147 3.1 Definition of goal

148 [Requirement]

149 • The product or system/technology of a study shall be clearly defined, when conducting the LCA.

150 [Recommendation]

151 • The reason for the calculation, party to report to, and reporting means should be clearly declared.

152

#### 153 3.2 Functional unit

154 [Requirement]

155 • A function and functional unit of the system/technology being studied shall be specified. A  
156 functional unit is a quantified function of the system in a certain unit.

157 • The period and geographical coverage for which GHG emission amount is determined shall be  
158 identified. For setting the period, the scientific basis for storage and sequestration of GHG by  
159 each CR2 technology shall be presented.

160

161 Note: Example of functional unit

162 Biochar: biochar mass of 1 kg

163 BECCS (Bioenergy with CCS): power generation of 1 kWh (power transmission end)

164 Afforestation: afforestation area of 1 ha

165

### 166 3.3 Scope of the assessment

167 [Requirement]

- 168 • Processes in an assessment (system boundary) shall be identified.
- 169 • In principle, all the energies, raw materials, and wastes to be used/disposed in processes shall be  
170 included in the introduction and emission of (input to and output from) the system border. The  
171 capital goods that constitute processes shall also be included in the system boundary.
- 172 • When part of the processes inside the system boundary is excluded, those processes and the  
173 reason for the exclusion shall be clearly stated.

174

### 175 3.4 GHG to be assessed and global warming potential

176 [Requirement]

- 177 • Seven GHG (carbon dioxide (CO<sub>2</sub>), methane (CH<sub>4</sub>), nitrogen monoxide (N<sub>2</sub>O),  
178 hydrofluorocarbon (HFCs), perfluorocarbon (PFCs), sulfur hexafluoride (SF<sub>6</sub>), and nitrogen  
179 trifluoride (NF<sub>3</sub>)) for which an agreement was made in the United Nations Framework  
180 Convention on Climate Change shall be subjects for the assessment.
- 181 • For the global warming potential of GHG, the latest potential in the assessment report and other  
182 documents of the Intergovernmental Panel on Climate Change shall be used. Among them, we  
183 recommend using the 100-year GWP (Global Warming Potential).

184 [Permitted matters]

- 185 • Only specific GHG may be assessed only when the reason is clearly presented.

186

### 187 3.5 Calculation methods

188 3.5.1 The amount of GHG generated from technologies using fossil fuel (first term on the  
189 right side of Formula (1))

190 [Requirement]

- 191 • When a CR2 technology system in the study captures GHG from technologies that use fossil fuel,  
192 the energies, raw materials thrown into the technologies, as well as industrial waste processing  
193 and others shall be included. At the same time, the amount of GHG emissions related to the  
194 production of the capital goods in the corresponding technologies shall also be included.

195 [Permitted matters]

- 196 • In principle, GHG generated from the production of capital goods are subject to the assessment,  
197 but capital goods that are not attributable to the implementation of the project and whose GHG

generated are considered to be much smaller than the GHG generated from the operation of technologies using fossil fuels may be excluded from the calculation. However, a rational explanation of the reason for such exclusion shall be provided.

3.5.2 The amount of GHG emissions due to introduction of CR2 technologies (second term on the right side of Formula (1))

[Requirement]

- GHG emissions due to the use of energy and raw materials, waste disposal, and others as a result of introduction of the CR2 technology shall be determined. At the same time, GHG emissions associated with the production of capital goods of the technology shall be determined.

[Permitted matters]

- In principle, GHG emissions from the production of capital goods are subject to the assessment, but capital goods that are not attributable to the implementation of the project and whose GHG emissions are considered to be much smaller than the GHG emissions from the operation of technologies using fossil fuels may be excluded from the calculation. However, a rational explanation of the reason for such exclusion shall be provided.

3.5.3 The amount of GHG stored/sequestered due to the introduction of CR2 technologies (third term on the right side of Formula (1))

Storage and sequestration of GHG captured by CR2 technologies include the geological storage of GHG by CCS, sequestration of GHG as a product by CCU, and sequestration of GHG dependent of a natural process.

Note 1: Sequestration as a product refers to GHG fixed through an artificial process. Such products may include synthetic fuel, concrete structure, and biochar. They also include temporary sequestration by CCU.

Note 2: Sequestration dependent of a natural process may include afforestation, cropland soil, blue carbon, and enhanced rock weathering.

Note 3: As with sequestration of GHG by biochar as a product, there are some cases in which natural processes must be considered, such as the conditions of the application site.

[Requirement]

- For geological storage of GHG by CCS, the actual amount of GHG stored shall be determined. In this case, the amount obtained by subtracting the amount of GHG leaked out to the atmosphere during the transportation and storage process from the amount of GHG captured shall be stated as the storage/sequestration amount.

- 234 • When sequestering GHG as a product through CCU:  
235 (1) Amount of GHG contained in products out of the amount captured  
236 (2) Amount of GHG obtained by subtracting the amount of GHG unused in products from  
237 the amount of GHG captured

238 The amount of GHG sequestered shall be determined by either of the above methods and clearly  
239 stated. The average GHG sequestration duration as a product shall be clearly addressed.

- 240 • When conducting assessments technologies involving natural processes, carbon sequestration  
241 sites (carbon pools) shall be defined, and the increase or decrease in the amount of carbon in the  
242 pool per time (accumulation or decomposition rate) and the activity data (e.g., the area of the  
243 storage site) shall be clarified.

244 [Recommendation]

- 245 • To store/sequester GHG through CCS or a natural process, the amount of leakage of GHG being  
246 stored/sequestered should be monitored.

- 247 • For technologies involving a natural process, major carbon pools should be included as much as  
248 possible.

249 [Permitted matters]

- 250 • If monitoring of the amount of GHG leakage during storage/sequestration is difficult, an estimate  
251 value may be used. For example, leakage due to decomposition during carbon sequestration by  
252 biochar may be determined using the percentage of carbon remaining after 100 years.

- 253 • When it is difficult to measure accumulation/decomposition rates when assessing GHG  
254 sequestration involving natural processes, the default values specified in the IPCC guidelines may  
255 be used.

256

### 257 3.6 Determination of cost of CR2 technologies

258 [Recommendation]

- 259 • The cost associated with CR2 technologies should be assessed.  
260 • When avoided GHG emissions are evaluated (Chapter 4), the cost per amount of avoided GHG  
261 emission should be appended.

262

### 263 3.7 Data collection and data quality

264 [Requirement]

- 265 • The data collection and data quality shall be compliant with ISO 14040:2006 standard, JIS Q  
266 14040:2010 and ISO 14044:2006 standards, and JIS Q 14044:2010.

267

### 268 3.8 Sensitivity analysis and uncertainty analysis

269 [Recommendation]

305 CR2 system in place.

306

307 Note 1: For the DACCS (Direct Air Capture and Carbon Storage) system, the zero-emission state  
308 before DACCS investment may be set as a reference.

309

310 • The functional unit and its quantity shall be the same between the first term on the right side of  
311 Formula (2) (GHG emission from reference system) and the second term on the right side of  
312 Formula (2) (GHG emission from CR2 system ).

313 • The scope of assessment must be the same between the first term on the right side of Formula (2)  
314 (GHG emission from reference system) and the second term on the right side of Formula (2)  
315 (GHG emission from CR2 system ).

316

317 [Recommendation]

318 • When there are multiple functional units in the system, each functional unit should be clearly  
319 stated.

320

321 Note: Example of multiple functional units (CCU)

322 Where CO<sub>2</sub> is captured in the cement production and methanol is produced using the captured  
323 CO<sub>2</sub> (Appendix 2), there are two functional units: 1 t of cement and 1 t of methanol.

324

325 [Permitted matters]

326 • When there are multiple functional units and when it is extremely difficult to observe, obtain, and  
327 estimate the data, only one functional unit may be assumed.

328 • When there are multiple functional units and the amount of GHG emissions/avoided emissions  
329 associated with a certain functional unit is considerably small, the corresponding functional unit  
330 may be ignored.

331 • In general, wide scope of the assessment is preferable. However, when the amounts of GHG  
332 emissions from both “reference system” and “CR2 system” are the same or when parts of the  
333 systems can be regarded as the same, those systems may be excluded from the scope of  
334 assessment with clear explanation.

335

336 Note 1: For methanol production, both methanol produced by an existing process and by CCU may  
337 be regarded to go through the same processes after shipment. The scope of assessment; therefore,  
338 may include only methanol production process, and exclude the processes after methanol  
339 shipment.

340

341 Note 2: In some cases, the main and co-products of a CR2 technology may contribute to significant  
342 GHG emission reductions, either indirectly or through ripple effects (e.g., reduction in chemical  
343 fertilizer use through soil plowing of biochar, reduction in GHG emissions from chemical  
344 fertilizer production). In such cases, the GHG emission reductions may be specifically and in  
345 detail described (and both positive and negative effects accounted for on a net basis) and  
346 accounted for as avoided GHG emissions by the CR2 technology.

## 347 **5. Report**

348 [Recommendation]

- 349 • When communicating the results of GHG emissions accounting with stakeholders and others, the  
350 communication method may vary depending on the purpose. The report for third parties should  
351 include the following requirements
  - 352 a. Definition of goal
  - 353 b. CR2 technology assessed
  - 354 c. Functional units (including storage period and geographical range)
  - 355 d. [Impact categories evaluated]
  - 356 e. Definition of scope
  - 357 f. List of GHG accounted and global warming potential applied
  - 358 g. Methodologies of determination of the amount of GHG storage/isolation and the results
  - 359 h. Data collection and calculation procedures
  - 360 i. Data quality
  - 361 j. Interpretation
  - 362 k. Critical review

## 363 **6. Critical review and verification**

364 [Recommendation]

- 365 • The report should be subject to critical review or verification. However, it is not necessarily  
366 limited to a third party.

## 367 **7. Glossary**

368 CCS (carbon dioxide capture and storage): process consisting of the separation of CO<sub>2</sub> from industrial  
369 and energy related sources, transportation, and injection into a geological formation, resulting in  
370 its long-term isolation from the atmosphere (ISO/TR27915:2017)

371 (Below are auxiliary explanation of CCS by ISO 27917.)

372 Note 1 to entry: CCS is often referred to as Carbon Capture and Storage. This terminology is not

373 encouraged because it is inaccurate: the objective is the capture of carbon dioxide and not the  
374 capture of carbon. Afforestation is another form of carbon capture that does not precisely describe  
375 the physical process of removing CO<sub>2</sub> from industrial emission sources.

376 Note 2 to entry: The term "sequestration" is also used alternatively to "storage". The term  
377 "storage" is preferred since "sequestration" is more generic and can also refer to biological  
378 processes (absorption of carbon by living organisms).

379 Note 3 to entry: Long term means the minimum period necessary for geological storage of CO<sub>2</sub>  
380 to be considered an effective and environmentally safe climate change mitigation option.

381 Note 4 to entry: The term Carbon dioxide Capture, Utilization (or use) and Storage (CCUS)  
382 include the concept that isolation from the atmosphere could be associated with a beneficial  
383 outcome. CCUS is embodied within the definition of CCS to the extent that long term isolation  
384 of CO<sub>2</sub> occurs through storage within geological formations. CCU is Carbon Capture and  
385 Utilization (or use) without storage within geological formations.

386 Note 5 to entry: CCS should also ensure long term isolation of CO<sub>2</sub> from oceans, lakes, potable  
387 water supplies and other natural resources.

388

389 Carbon Dioxide Removal (CDR): Human activity capturing carbon dioxide (CO<sub>2</sub>) from the  
390 atmosphere and durably storing it in geological, terrestrial, or ocean reservoirs, or in products. It  
391 includes enhancement of biological or geochemical CO<sub>2</sub> sinks and direct air carbon capture and  
392 storage (DACCS), but excludes natural CO<sub>2</sub> uptake not directly caused by human activities  
393 (Smith et al. 2024).

394

395 GHG (greenhouse gas): gaseous constituent of the atmosphere, natural or anthropogenic, that absorbs  
396 and emits radiation at specific wavelengths within the spectrum of infrared radiation emitted by  
397 the Earth's surface, the atmosphere, and clouds (ISO/TR27915:2017)

398

399 GHG removal: total mass of GHG removed from the atmosphere over a specified period of time  
400 (ISO/TR27915:2017)

401

402 GHG/CO<sub>2</sub> emission reduction: calculated net decrease of GHG emissions between a baseline  
403 scenario and the output assessment target technology (ISO/TR27915:2017)

404

405 CCU (carbon dioxide capture and utilization): act of capturing carbon dioxide (CO<sub>2</sub>) in exhaust gas or  
406 the atmosphere and converting it into products.

407

452 **Appendix 2. GHG emissions and avoided emissions in CCU system that uses raw fossil**  
 453 **fuel**

454 Figure A-2. Example of GHG emissions and avoided emissions in CCU system that uses raw fossil  
 455 fuel (two functional units)

456

457 Appendix 3. GHG emission from DAC + CCU system (removal if the value is negative)

Emission (emission from DAC + CCU system)  
 = (Amount of GHG generated by technologies that use fossil fuel) + (Amount of GHG emission from introduced CR2 technologies) – (Amount of GHG stored/sequestered by CR2 technologies)  
 = (CO<sub>2</sub> generated from fossil fuel) + (Emission from DAC/transportation equipment + Emission from MeOH manufacturing facility) – (CO<sub>2</sub> stored in MeOH product)  
 = 0.55 + (0.01 + 0.025) – 1.45  
 = -0.865 t of CO<sub>2</sub>/t of MeOH = Move in/out across boundary (0.1 + 0.01 + 0.1 + 0.025 – 1.1)

458 Figure A-3. Example of GHG emission from DAC + CCU system (removal if the value is negative)

459

460 Appendix 4 GHG emission from DAC + CCS system (or removal if the value is negative)

Amount of Emission = (Amount of GHG generated from technologies that use fossil fuel) + (Amount of GHG emission from introduced CR2 technologies) – (Amount of GHG stored/sequestered by introduced CR2 technologies)  
 = (CO<sub>2</sub> generated from fossil fuel that is used by DAC) + (Emission from DAC/transportation equipment + emission from storage facility) – (Amount of CO<sub>2</sub> storage)  
 = 0.4 + (0.01 + 0.02) – (1.0)  
 = -0.57 t of CO<sub>2</sub>/t of CO<sub>2</sub> stored = Move in/out across boundary (0.1 + 0.01 + 0.1 + 0.02 – 0.8)

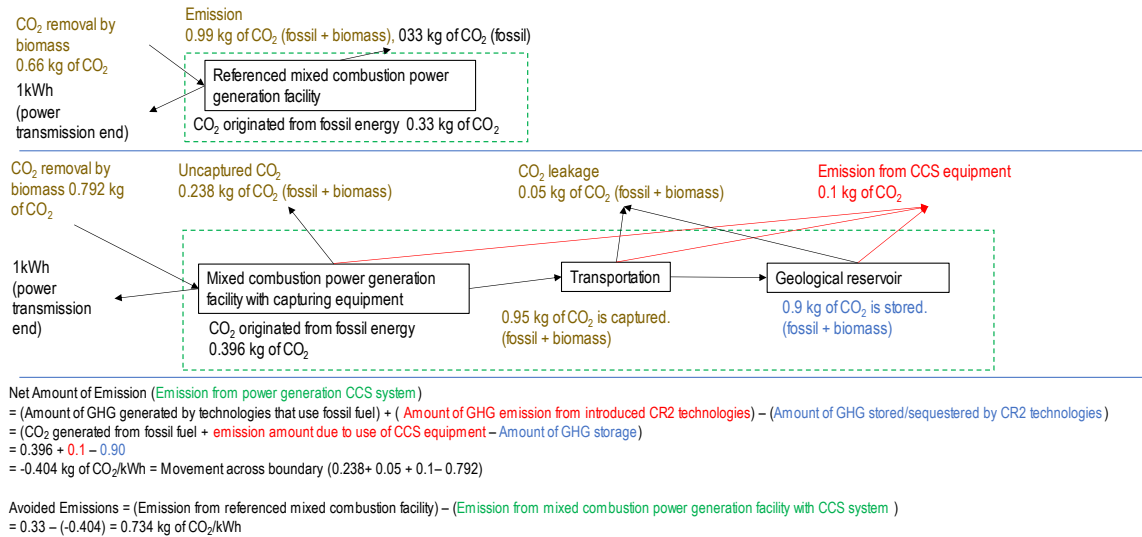

461

462 Figure A-4. Example of GHG Emission from DAC + CCS system (or removal if the value is  
 463 negative)

464

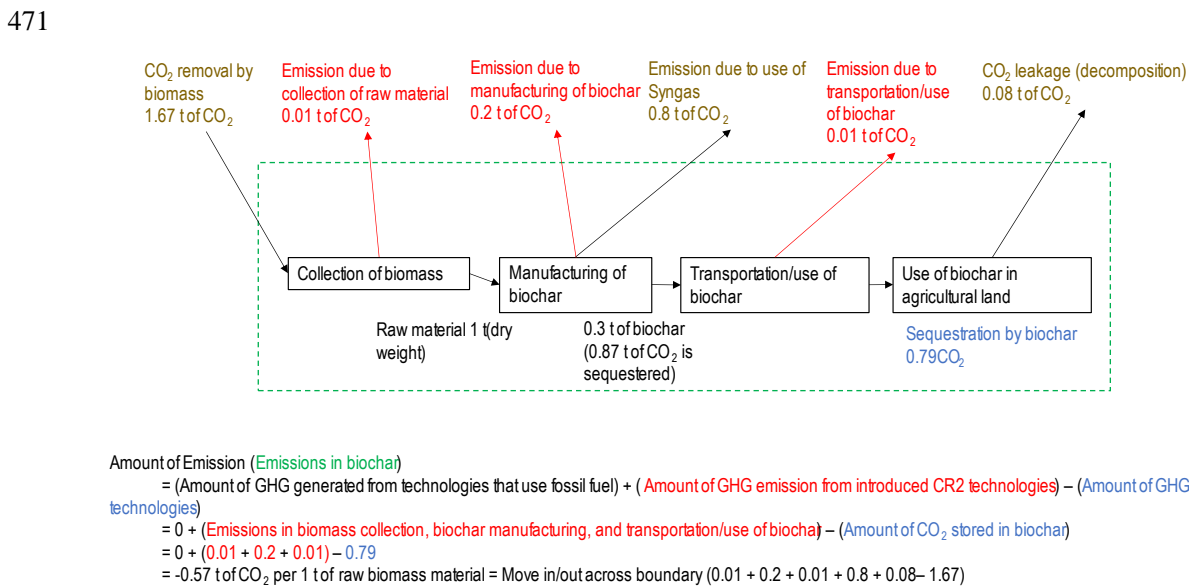

465 Appendix 5. GHG emission (or removal if the value is negative) and avoided emissions in  
466 mixed combustion BECCS (fossil: biomass = 1:2) system

467 Figure A-5. Example of GHG emission (or removal if the value is negative) and avoided emissions in  
468 mixed combustion BECCS (fossil: biomass = 1:2) system

469 Appendix 6. GHG emission accounting in biochar (or removal if the value is negative)

472 Figure A-6. Example of GHG emission accounting in biochar (or removal if the value is negative)
